بِسْمِ اللَّهِ الرَّحْمَنِ الرَّحِيمِ

Cartesian (Rectangular) Coordinates $\{\underline{x}_i\}$:

Consider a particle traveling in a Cartesian coordinates:

$$\underline{r} = x_1 \underline{e}_1 + x_2 \underline{e}_2 + x_3 \underline{e}_3 = x_i \underline{e}_i \quad (\text{Position Vector}) \quad (3.10)$$

$$\Delta \underline{r} = \underline{r}^* - \underline{r} \equiv \Delta x_i \underline{e}_i = (x_i^* - x_i) \underline{e}_i \quad (\text{Particle Displacement}) \quad (3.11)$$

$$\underline{v} = \frac{d\underline{r}}{dt} = \underline{\dot{r}} \equiv v_i \underline{e}_i = \dot{x}_i \underline{e}_i$$

(Particle Velocity) (3.12)

$$\underline{a} = \underline{\dot{v}} = \underline{\ddot{r}} \equiv a_i \underline{e}_i = \ddot{x}_i \underline{e}_i$$

(Particle Acceleration) (3.13)

Remark: If A and B are two different reference points in a single reference frame, then; velocity and acceleration measures would be independent of the reference point.

$$\underline{r}_{P/A} = \underline{r}_{B/A} + \underline{r}_{P/B} \quad \text{where} \quad \underline{r}_{B/A} = \text{const.}$$

$$\dot{\underline{r}}_{P/A} = \dot{\underline{r}}_{P/B} \quad \text{where} \quad \dot{\underline{r}}_{B/A} = 0$$

$$\underline{v}_{P/A} = \underline{v}_{P/B} = \underline{v}_P$$

$$\underline{a}_{P/A} = \underline{a}_{P/B} = \underline{a}_P$$

Example: Write the position vector of the point “A” in terms of the shown parameter (θ)?

Solution:

$$\overline{BC} = R \sin \theta$$

$$\overline{OC} = R \cos \theta$$

$$\overline{AC} = \sqrt{L^2 - \overline{BC}^2} = R \sqrt{\left(\frac{L}{R}\right)^2 - \sin^2 \theta}$$

$$\underline{r}^A(\theta) = [\overline{OC} + \overline{AC}] \underline{e}_2 = R(\cos \theta + \sqrt{\left(\frac{L}{R}\right)^2 - \sin^2 \theta}) \underline{e}_2$$

Example: An inextensible cord, wrapped around a cylinder, is pulled up as the cylinder rolls without slipping on a level ground. Determine the position, velocity, and acceleration vectors of the tip of the cord in terms of the parameter (θ) and its corresponding derivatives.

Solution:

1. Inextensibility of the cord implies that:

$$\overline{PA} = \overline{P_0 A_0} = \frac{\pi}{2} R$$

2. Rolling without slipping means that:

$$\overline{P_0 E} = \overline{PE} = R\theta$$

3. From 1 and 2, we have:

$$\overline{DA} = \overline{PA} - \overline{PD} = \frac{\pi}{2} R - \left(\frac{\pi}{2} - \theta\right) R = R\theta$$

$$\overline{O_0 D} = \overline{P_0 E} - \overline{OD} = R\theta - R = R(\theta - 1)$$

hence,

$$\underline{r}_A(\theta) = \overline{P_0 O_0} \underline{e}_2 + \overline{O_0 D} \underline{e}_1 + \overline{DA} \underline{e}_2 = R \underline{e}_2 + R(\theta - 1) \underline{e}_1 + R\theta \underline{e}_2$$

Position vector:

$$\underline{r}_A(\theta) = R(\theta - 1) \underline{e}_1 + R(\theta + 1) \underline{e}_2$$

Velocity vector:

$$\underline{v}_A = \dot{\underline{r}}_A = R\dot{\theta} \underline{e}_1 + R\dot{\theta} \underline{e}_2 = R\dot{\theta}(\underline{e}_1 + \underline{e}_2)$$

Acceleration vector:

$$\underline{a}_A = \dot{\underline{v}}_A = \ddot{\underline{r}}_A = R\ddot{\theta}(\underline{e}_1 + \underline{e}_2)$$

Example: The recording pen is used to draw the line QP on graph paper by an automatic x-y recorder. The velocity of the carriage AB is given as $\dot{x} = 2t + 4$ (ft/s) and the velocity of the pen relative to carriage AB is $\dot{y} = 2/y$ (ft/s). At time $t = 0$ the pen is at the position $(x, y) = (1, 0)$. Determine (a) the equation for the shape of the graph, (b) the velocity and acceleration of point P at $t = 2$ s, and (c) the slope of the graph at $t = 2$ s.

Solution:

$$\frac{dx}{dt} = 2t + 4 \Rightarrow dx = 2t dt + 4 dt \Rightarrow$$

$$\frac{dy}{dt} = \frac{2}{y} \Rightarrow y dy = 2 dt \Rightarrow$$

$$t = y^2 / 4$$

$$x = \frac{1}{16} y^4 + y^2 + 1 \quad \text{ft}$$

Solution:

$$x = \frac{1}{16} y^4 + y^2 + 1 \quad \text{ft}$$

$$\underline{v} = 8\underline{i} + 0.707\underline{j} \quad \text{ft/s}$$

$$\underline{a} = 2\underline{i} - 0.177\underline{j} \quad \text{ft/s}^2$$

$$\frac{dy}{dx} = \frac{0.707}{8} = 0.0884 \cong 5^\circ$$

Changing Relativity (Mapping), and Transformations:

In dynamics, it is sometimes helpful or necessary to describe/transform components of a vector previously defined in one coordinate frame into the another set of coordinates.

Let us consider a general situation where two coordinate systems, $\{x_1, x_2, x_3\}$ and $\{\bar{x}_1, \bar{x}_2, \bar{x}_3\}$, are employed to represent the components of a vector.

(Only orientation of the axes is of interest here, so the origins of the coordinate systems coincide).

Given: Suppose \underline{P}^* is known in the coordinate frame $\{\bar{x}_j\}$,

Find: Define \underline{P} in the coordinate frame $\{ \quad \}$?

It can be shown that:

$$\underline{P} = \underline{T} \underline{P}^* \quad or \quad \{P_i\}_x = [\ell_{ij}] \{\bar{P}_j\}_{\bar{x}} \quad (3.14)$$

$$\underline{\underline{T}} =$$

where:

$$\underline{\underline{T}} = [\ell_{ij}] = \begin{bmatrix} l_{1\bar{1}} & l_{1\bar{2}} & l_{1\bar{3}} \\ l_{2\bar{1}} & l_{2\bar{2}} & l_{2\bar{3}} \\ l_{3\bar{1}} & l_{3\bar{2}} & l_{3\bar{3}} \end{bmatrix} \equiv \underline{\underline{(Matrix\ of\ Direction\ Cosines)}} \quad (3.15)$$

$$\ell_{ij} = \cos(x_i, \bar{x}_j), \quad (i.e. \quad l_{1\bar{1}} = \underline{e}_1 \cdot \bar{\underline{e}}_1 = |\underline{e}_1| |\bar{\underline{e}}_1| \cos(\underline{e}_1, \bar{\underline{e}}_1) = \cos(x_1, \bar{x}_1) \quad)$$

Columns of $\underline{\underline{T}} \nexists \ell_{ij}$ are:

the projection of the unit vectors of \bar{x}_j into x_i

Rows of $\underline{\underline{T}} \nexists \ell_{ij}$ are:

the projection of the unit vectors of x_i into \bar{x}_j

When the origins coincide, $\underline{\underline{T}}$ is a Rotation Matrix, and Orthogonal,
Expressing the relative orientation of frame $\{ \bar{x}_j \}$ with respect to $\{ x_i \}$.

Inverse of an Orthogonal matrix is equal to its Transpose: ($\underline{\underline{T}}^{-1} = \underline{\underline{T}}^t$)

(Orthogonal Matrices are those in which the *dot products* of any
of its two columns are equal to *zero*, and the *magnitude* of each
one of its columns is equal to *unity*).

Elementary Rotation Matrices:

Rotation transformations about the coordinate axes are called the Elementary Rotation Matrices, and they are defined as follows:

$$\underline{T}_1(x_1, \theta_1) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \theta_1 & -\sin \theta_1 \\ 0 & \sin \theta_1 & \cos \theta_1 \end{bmatrix} \Rightarrow \underline{x} = \underline{T}_1 \underline{\bar{x}}$$

$$\underline{T}_2(x_2, \theta_2) = \begin{bmatrix} \cos \theta_2 & 0 & \sin \theta_2 \\ 0 & 1 & 0 \\ -\sin \theta_2 & 0 & \cos \theta_2 \end{bmatrix} \Rightarrow \underline{x} = \underline{T}_2 \bar{\underline{x}}$$

$$\underline{\underline{T}}_3(x_3, \theta_3) = \begin{bmatrix} \cos \theta_3 & -\sin \theta_3 & 0 \\ \sin \theta_3 & \cos \theta_3 & 0 \\ 0 & 0 & 1 \end{bmatrix} \Rightarrow \underline{x} = \underline{\underline{T}}_3 \underline{\bar{x}}$$

Ex: Determine the matrix of direction cosines between coordinates

$\{x_i\}$ and $\{\bar{x}_j\}$.

Solution:

$$\underline{\underline{T}} = [\ell_{ij}] = \begin{bmatrix} \ell_{1\bar{1}} & \ell_{1\bar{2}} \\ \ell_{2\bar{1}} & \ell_{2\bar{2}} \end{bmatrix} = [\cos(x_i, x_j)] = \begin{bmatrix} \cos(1, \bar{1}) & \cos(1, \bar{2}) \\ \cos(2, \bar{1}) & \cos(2, \bar{2}) \end{bmatrix}$$

$$\underline{\underline{T}} = \begin{bmatrix} \cos 30 & -\sin 30 \\ \sin 30 & \cos 30 \end{bmatrix} = \begin{bmatrix} 0.866 & -0.5 \\ 0.5 & 0.866 \end{bmatrix}$$

Therefore, if :

$$\bar{P} = 1\bar{e}_1 + 1\bar{e}_2 \quad \Rightarrow \quad \underline{P} = \underline{\underline{T}} \bar{P} = \begin{bmatrix} 0.866 & -0.5 \\ 0.5 & 0.866 \end{bmatrix} \begin{bmatrix} 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0.366 \\ 1.366 \end{bmatrix}$$

Ex: A slender bar lies in the first quadrant of the (x_1-x_2) plane. One of its tips, A, is at the origin. The angular position with respect to x_1 -axis is “ θ ”. A bead slides on the slender rod at a distance “R” from A and slides out at a speed “v”. Determine the velocity of the bead expressed in frame $\{x_i\}$ for the cases when:

(a)- the rod is fixed?

(b)- the rod spins in the (x_1-x_2) plane about A at an angular velocity $\dot{\theta}$?

Solution:

Let $\{y_j\}$ be another coordinate set such that y_1 coincides with the rod, and y_3 with x_3 .

$$\{x_i\} = \underline{\underline{T}}\{y_j\} \quad \text{where : } \underline{\underline{T}} = \begin{bmatrix} C\theta & -S\theta & 0 \\ S\theta & C\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Therefore, position of the bead in $\{x_i\}$ coordinate is:

$$\begin{Bmatrix} x_1 \\ x_2 \\ x_3 \end{Bmatrix} = \begin{bmatrix} C\theta & -S\theta & 0 \\ S\theta & C\theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} R \\ 0 \\ 0 \end{bmatrix} = \begin{Bmatrix} RC\theta \\ RS\theta \\ 0 \end{Bmatrix}$$

(a)- when $\theta = \text{constant}$, $\Rightarrow \underline{v} = \begin{Bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \end{Bmatrix} = \underline{\underline{T}} \begin{bmatrix} v \\ 0 \\ 0 \end{bmatrix} = \begin{Bmatrix} vC\theta \\ vS\theta \\ 0 \end{Bmatrix}$

(b)- when θ varies with time,

$$\underline{v} = \{v_i\}_x = \{\dot{x}_i\} = \underline{\dot{T}} \begin{bmatrix} R \\ 0 \\ 0 \end{bmatrix} + \underline{T} \begin{bmatrix} \dot{R} \\ 0 \\ 0 \end{bmatrix}$$

Velocity in $\{x_i\}$ coordinate:

$$\{\underline{v}\}_x = \{v_i\}_x = \begin{bmatrix} -\dot{\theta}S\theta & -\dot{\theta}C\theta & 0 \\ \dot{\theta}C\theta & -\dot{\theta}S\theta & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} R \\ 0 \\ 0 \end{bmatrix} + \underline{T} \begin{bmatrix} v \\ 0 \\ 0 \end{bmatrix} = \begin{Bmatrix} vC\theta - R\dot{\theta}S\theta \\ vS\theta + R\dot{\theta}C\theta \\ 0 \end{Bmatrix}$$

Velocity in $\{y_j\}$ coordinate:

$$\{\underline{v}\}_y = \{v_j\}_y = \underline{T}^t \{v_i\}_x = \begin{bmatrix} C\theta & S\theta & 0 \\ -S\theta & C\theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \{v_i\}_x = \begin{Bmatrix} v \\ R\dot{\theta} \\ 0 \end{Bmatrix}$$

ORTHOGONAL CURVILINEAR COORDINATES

Description specifies the position of a point, by giving the value of **3-parameters**, q^a , (i.e. θ, φ, R) which form an **orthogonal mesh** in space.

There exist a unique transformation between the Cartesian Coordinates (x, y, z) and the Orthogonal Coordinates, q^a , (i.e. θ, φ, R), such that:

$$x = x(\theta, \varphi, R), \quad y = y(\theta, \varphi, R), \quad z = z(\theta, \varphi, R) \\ (3.16)$$

$$\theta = \theta(x, y, z), \quad \varphi = \varphi(x, y, z), \quad R = R(x, y, z) \\ (3.17)$$

$$\mathbf{x} = \mathbf{x}(\theta, \phi, R), \quad \mathbf{y} = \mathbf{y}(\theta, \phi, R), \quad \mathbf{z} = \mathbf{z}(\theta, \phi, R) \quad (3.16)$$

$$\theta = \theta(\mathbf{x}, \mathbf{y}, \mathbf{z}), \quad \phi = \phi(\mathbf{x}, \mathbf{y}, \mathbf{z}), \quad R = R(\mathbf{x}, \mathbf{y}, \mathbf{z}) \quad (3.17)$$

When two of the parameters of \mathbf{q}^a (i.e. θ, ϕ, R) are held constant while the third is given a range of values, the first group of equations (16) and (17) specifies a curve in space in parametric form.

When the constant parameter pair is given a variety of values, the result is a family of curves. Repeating this procedure with each of the other pairs of parameters held constant, produces two more families of curves (i.e. called mesh). The families of curves are mutually Orthogonal.

They are named after one of the types of surfaces on which one of the curvilinear coordinates is constant.

$$\left\{ \begin{array}{l} X = X(R, \varphi_1, Z_1) \\ X = X(R, \varphi_2, Z_2) \\ \vdots \\ X = X(R, \varphi_i, Z_i) \end{array} \right.$$

$$\left\{ \begin{array}{l} X = X(R_1, \varphi, Z_1) \\ X = X(R_2, \varphi, Z_2) \\ \vdots \\ X = X(R_i, \varphi, Z_i) \end{array} \right.$$

$$\left\{ \begin{array}{l} X = X(R_1, \varphi_1, Z) \\ X = X(R_2, \varphi_2, Z) \\ \vdots \\ X = X(R_i, \varphi_i, Z) \end{array} \right.$$

$$\left\{ \begin{array}{l} X = X(\theta, \varphi_1, R_1) \\ X = X(\theta, \varphi_2, R_2) \\ \vdots \\ X = X(\theta, \varphi_i, R_i) \end{array} \right.$$

$$\left\{ \begin{array}{l} X = X(\theta_1, \varphi, R_1) \\ X = X(\theta_2, \varphi, R_2) \\ \vdots \\ X = X(\theta_i, \varphi, R_i) \end{array} \right.$$

$$\left\{ \begin{array}{l} X = X(\theta_1, \varphi_1, R) \\ X = X(\theta_2, \varphi_2, R) \\ \vdots \\ X = X(\theta_i, \varphi_i, R) \end{array} \right.$$

Cylindrical Coordinates (R, ϕ , Z):

Base Vectors are: $\{\underline{x}_R, \underline{x}_\phi, \underline{x}_Z\}$

\underline{e}_R : unit vector in the direction of increasing R,

\underline{e}_ϕ : unit vector in the direction of increasing ϕ ,

\underline{e}_Z : unit vector in the direction of increasing Z.

Position Vector:

$$\underline{r}_{P/O} = R\underline{e}_R + Z\underline{e}_Z \quad (3.18)$$

Velocity Vector:

$$\underline{v}_P = \dot{R}\underline{e}_R + R\dot{\underline{e}}_R + \dot{Z}\underline{e}_Z + Z\dot{\underline{e}}_Z$$

unit vectors $\{\underline{e}_R, \underline{e}_\phi, \underline{e}_Z\}$ all rotate with an angular velocity “ $\dot{\phi}$ ”,

then using Jaumann Rate, we have:

$$\dot{\underline{e}}_R = \underline{\omega}_R \times \underline{e}_R = (\dot{\phi}\underline{e}_Z) \times (\underline{e}_R) = \dot{\phi}\underline{e}_\phi \quad \text{and} \quad \dot{\underline{e}}_Z = 0$$

$$\underline{v}_P = \dot{R}\underline{e}_R + R\dot{\phi}\underline{e}_\phi + \dot{Z}\underline{e}_Z \quad (3.19)$$

Acceleration Vector:

$$\underline{a}_P = \ddot{R}\underline{e}_R + \dot{R}\dot{\underline{e}}_R + \dot{R}\dot{\phi}\underline{e}_\phi + R\ddot{\phi}\underline{e}_\phi + R\dot{\phi}\dot{\underline{e}}_\phi + \ddot{Z}\underline{e}_Z + \dot{Z}\dot{\underline{e}}_Z$$

$$\dot{\underline{e}}_\phi = \underline{\omega}_\phi \times \underline{e}_\phi = (\dot{\phi}\underline{e}_Z) \times (\underline{e}_\phi) = -\dot{\phi}\underline{e}_R \quad \text{and} \quad \dot{\underline{e}}_Z = 0$$

$$\underline{a}_P = (\ddot{R} - R\dot{\phi}^2)\underline{e}_R + (2\dot{R}\dot{\phi} + R\ddot{\phi})\underline{e}_\phi + \ddot{Z}\underline{e}_Z = a_R\underline{e}_R + a_\phi\underline{e}_\phi + a_Z\underline{e}_Z \quad (3.20)$$

a_R : Radial Acceleration

a_ϕ : Transverse Acceleration

a_Z : Axial Acceleration

$2\dot{R}\dot{\phi}$: Coriolis Acceleration (due to the simultaneous change in “R” and “ ϕ ” with respect to time).

مختصر
